

MA385 Part 4: Linear Algebra 2

4.3: Condition Numbers

Dr Niall Madden

November 2025

1. Outline Section 4.3

- | | | | |
|---|------------------------------------|---|--|
| 1 | Motivation | 4 | Condition Numbers |
| 2 | Consistency of matrix norms | 5 | Calculating κ_∞ and κ_1 |
| 3 | Computer representation of numbers | 6 | Estimating κ_2 |
| | | 7 | Exercises |

For more, see Section 2.7 of Suli and Mayers:

<https://ebookcentral.proquest.com/lib/nuig/reader.action?docID=221072&ppg=51&c=UERG>

2. Motivation

Numerical solutions to some linear systems are adversely affected by round-off errors.

This phenomenon is due to the *matrices* in the linear systems. Those matrices for which the issue is particularly prevalent are referred to as being **ill-conditioned**.

For any matrix, we can assign a numerical *score* that gives an indication of whether it is ill-conditioned. That score, called the **condition number**, is defined in terms of matrix norms, and is the subject of these section.

3. Consistency of matrix norms

Suppose we have a vector norm, $\|\cdot\|$ and associated subordinate matrix norm. It is not hard to see that

$$\|A\mathbf{u}\| \leq \|A\|\|\mathbf{u}\| \quad \text{for any } \mathbf{u} \in \mathbb{R}^n, A \in \mathbb{R}^{n \times n}.$$

Here is why:

By definition

$$\|A\| := \max_{\mathbf{u} \in \mathbb{R}^n, \|\mathbf{u}\|=1} \frac{\|A\mathbf{u}\|}{\|\mathbf{u}\|}$$

So, for any vector \mathbf{u} ,

$$\|A\| \geq \frac{\|A\mathbf{u}\|}{\|\mathbf{u}\|}$$

$$\Rightarrow \|A\| \cdot \|\mathbf{u}\| \geq \|A\mathbf{u}\|.$$

3. Consistency of matrix norms

There is an analogous statement for the product of two matrices:

Definition 4.3.1 (Consistent matrix norm)

A matrix norm $\|\cdot\|$ is **consistent** (or “*sub-multiplicative*”) if

$$\|AB\| \leq \|A\|\|B\|, \quad \text{for all } A, B \in \mathbb{R}^{n \times n}.$$

Theorem 4.3.1

Any subordinate matrix norm is consistent.

The proof is left to an exercise. That exercises also demonstrates that there are matrix norms which are *not* consistent.

4. Computer representation of numbers

[Please read this slide in your own time!]

Modern computers don't store numbers in decimal (base 10), but in binary (base 2) “floating point numbers” of the form :

$$x = \pm a \times 2^{b-M}.$$

Most use *double precision*, where 8 bytes (64 bits or *binary digits*) are used to store

- ▶ the sign (1 bit),
- ▶ a , called the “significand” or “mantissa” (52 bits)
- ▶ and the exponent, $b - 1023$ (11 bits)

Note that a has roughly 16 decimal digits.

(Some older computer systems sometimes use *single precision* where a has 23 bits — giving 8 decimal digits — and b has 7; so too do many new GPU-based systems).

4. Computer representation of numbers

When we try to store a real number x on a computer, we actually store the nearest floating-point number. That is, we end up storing $x + \delta x$, where δx is the “round-off” error.

But the quantity we are mainly interested in is the **relative error**: $|\delta x|/|x|$.

Since this is not a course on computer architecture, we'll simplify a little and just take it that single and double precision systems lead to a relative error of 10^{-8} and ~~10^{-16}~~ respectively.

5. Condition Numbers

(See p68–70 of Süli and Mayers for a full development of the concept of a condition number).

Suppose we use, say, LU -factorization and back-substitution on a computer to solve

$$A\mathbf{x} = \mathbf{b}.$$

Because of the “round-off error” we actually solve

$$A(\mathbf{x} + \delta\mathbf{x}) = (\mathbf{b} + \delta\mathbf{b}).$$

Our problem now is, for a given A , if we know the (relative) error in \mathbf{b} , can we find an upper-bound on the relative error in \mathbf{x} ?

5. Condition Numbers

Definition 4.3.2

The *condition number* of a matrix, with respect to a particular matrix norm $\|\cdot\|_*$ is

$$\kappa_*(A) = \|A\|_* \|A^{-1}\|_*.$$

If $\kappa_*(A) \gg 1$ then we say A is *ill-conditioned*.

Example: Find the condition number κ_∞ of

$$A = \begin{pmatrix} 10 & 12 \\ 0.08 & 0.1 \end{pmatrix}, \quad A^{-1} = \begin{pmatrix} 2.5 & 300 \\ -2 & 250 \end{pmatrix}$$

$$\text{Then } \|A\|_\infty = 22 \quad \|A^{-1}\|_\infty = 302.5$$

$$\text{So } \kappa_\infty(A) = (22)(302.5) = 6655.$$

5. Condition Numbers

Theorem 4.3.2

Suppose that $A \in \mathbb{R}^{n \times n}$ is nonsingular and that $\mathbf{b}, \mathbf{x} \in \mathbb{R}^n$ are non-zero vectors. If $A\mathbf{x} = \mathbf{b}$ and $A(\mathbf{x} + \delta\mathbf{x}) = (\mathbf{b} + \delta\mathbf{b})$ then

$$\frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leq \kappa(A) \frac{\|\delta\mathbf{b}\|}{\|\mathbf{b}\|}.$$

Since

$$A\mathbf{x} = \mathbf{b}$$

And

$$A(\mathbf{x} + \delta\mathbf{x}) = \mathbf{b} + \delta\mathbf{b}, \text{ so } A\mathbf{x} + A\delta\mathbf{x} = \mathbf{b} + \delta\mathbf{b},$$

we get

$$A\delta\mathbf{x} = \delta\mathbf{b}$$

Next

$$A\mathbf{x} = \mathbf{b} \Rightarrow \|A\mathbf{x}\| = \|\mathbf{b}\|.$$

$$\Rightarrow \|\mathbf{b}\| \leq \|A\| \cdot \|\mathbf{x}\|$$

5. Condition Numbers

Theorem 4.3.2

Suppose that $A \in \mathbb{R}^{n \times n}$ is nonsingular and that $\mathbf{b}, \mathbf{x} \in \mathbb{R}^n$ are non-zero vectors. If $A\mathbf{x} = \mathbf{b}$ and $A(\mathbf{x} + \delta\mathbf{x}) = (\mathbf{b} + \delta\mathbf{b})$ then

$$\frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leq \kappa(A) \frac{\|\delta\mathbf{b}\|}{\|\mathbf{b}\|}.$$

Similarly $A\delta\mathbf{x} = \delta\mathbf{b} \Rightarrow \delta\mathbf{x} = A^{-1}\delta\mathbf{b}.$

$$\Rightarrow \|\delta\mathbf{x}\| \leq \|A^{-1}\| \cdot \|\delta\mathbf{b}\|$$

Since we had $\|\mathbf{b}\| \leq \|A\| \cdot \|\mathbf{x}\|$

$$\Rightarrow \|\delta\mathbf{x}\| \cdot \|\mathbf{b}\| \leq \underbrace{\|A\| \cdot \|A^{-1}\|}_{\kappa(A)} \cdot \|\delta\mathbf{b}\| \cdot \|\mathbf{x}\|$$

$$\Rightarrow \frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leq \kappa(A) \frac{\|\delta\mathbf{b}\|}{\|\mathbf{b}\|}.$$

6. Calculating κ_∞ and κ_1

Example 4.3.1

Suppose we are using a computer to solve $A\mathbf{x} = \mathbf{b}$ where

$$A = \begin{pmatrix} 10 & 12 \\ 0.08 & 0.1 \end{pmatrix} \quad \text{and } \mathbf{b} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}.$$

But, due to round-off error, right-hand side has a relative error (in the ∞ -norm) of 10^{-6} . Give a bound for the relative error in \mathbf{x} in the ∞ -norm.

We had that $\kappa_\infty(A) = 6.655$

Since $\frac{\|\delta \mathbf{b}\|}{\|\mathbf{b}\|} = 10^{-6}$

So $\frac{\|\delta \mathbf{x}\|}{\|\mathbf{x}\|} \leq 6.655 \times 10^{-3}$

6. Calculating κ_∞ and κ_1

For every matrix norm we get a different condition number.

Example 4.3.2

Let A be the $n \times n$ matrix

$$A = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 \\ 1 & 1 & 0 & \dots & 0 \\ 1 & 0 & 1 & \dots & 0 \\ \vdots & & & & \\ 1 & 0 & 0 & \dots & 1 \end{pmatrix}.$$

What are $\kappa_1(A)$, and $\kappa_\infty(A)$?

First we compute $\|A\|_1$ and $\|A\|_\infty$.

$$\|A\|_1 = 2 \qquad \|A\|_\infty = n.$$

6. Calculating κ_∞ and κ_1

For this very special example, it is easy to write down the inverse of A :

$$A^{-1} = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 \\ -1 & 1 & 0 & \dots & 0 \\ -1 & 0 & 1 & \dots & 0 \\ \vdots & & & & \\ -1 & 0 & 0 & \dots & 1 \end{pmatrix}.$$

$$\|A^{-1}\|_1 = 2$$

$$\|A^{-1}\|_\infty = n$$

$$\Rightarrow \kappa_1(A) = 4 \qquad \kappa_\infty(A) = n^2$$

7. Estimating κ_2

To compute $\kappa_1(A)$ and $\kappa_\infty(A)$, we need to know A^{-1} , which is usually not practical. However, for κ_2 , we are able to *estimate* the condition number of A without knowing A^{-1} .

Recall that $\|A\|_2 = \sqrt{\lambda_n}$ where λ_n is the largest eigenvalue of $B = A^T A$.

We can also show that $\|A^{-1}\|_2 = \frac{1}{\sqrt{\lambda_1}}$ where λ_1 is the smallest eigenvalue of B

- ▶ $A^T A$ and AA^T have the same eigenvalues (they are "similar"):
 $A^T A x = \lambda x \Rightarrow A(A^T A)x = \lambda (Ax)$
 $\Rightarrow (AA^T)(Ax) = \lambda (Ax) \Rightarrow \lambda$ is an e'val of AA^T with e'vec Ax
- ▶ For any non-singular matrix X , we have that $(X^T)^{-1} = (X^{-1})^T$.
- ▶ $(A^T A)^{-1} = (AA^T)^{-1}$

7. Estimating κ_2

So

$$\kappa_2(A) = \left(\lambda_n / \lambda_1 \right)^{1/2}.$$

.....
Motivated by this, we'll finish MA385, by studying an easy way of estimating the eigenvalues of a matrix.

Finished here

8. Exercises

Exercise 4.3.1

- (i) Prove that, if $\|\cdot\|$ is a subordinate matrix norm, then it is *consistent*, i.e., for any pair of $n \times n$ matrices, A and B , we have $\|AB\| \leq \|A\|\|B\|$.
- (ii) One might think it intuitive to define the “max” norm of a matrix as follows:

$$\|A\|_{\infty} = \max_{i,j} |a_{ij}|.$$

Show that this is indeed a norm on $\mathbb{R}^{n \times n}$. Show that, however, it is not consistent.

8. Exercises

Exercise 4.3.2

Let A be the matrix

$$A = \begin{pmatrix} 0.1 & 0 & 0 \\ 10 & 0.1 & 10 \\ 0 & 0 & 0.1 \end{pmatrix}$$

Compute $\kappa_{\infty}(A)$. Suppose we wish to solve the system of equations $A\mathbf{x} = \mathbf{b}$ on *single precision* computer system (i.e., the relative error in any stored number is approximately 10^{-8}). Give an upper bound on the relative error in the computed solution \mathbf{x} .
